

I am trying to establish a process that joins truncated tetrahedrons in a chain that will roughly follow a line that I specify and can later update.

I plan to do this by analysing the four mirrored shapes (see left) as options for continuing the chain. I will do this by finding the 'mirrored option' whose centroid is closest to a point on the divided curve that I specify. The closest option will then be analysed in the same way to continue the chain. I hope to be able to control the chain length by manipulating the number of repetitions of this process.

Brep (Brep)

Object contains no warnings and 1 error

Error: Data conversion failed from Number to Brep

This is what I hope it will look like.

I have managed to isolate the closest new geometry from the list of options. The problem is that when I extract this data I cannot use this number to inform my shape (mirror the correct face to produce a new Brep).

Any suggestions would be greatly appreciated!
